Question 1

- (a) In a balanced growth path, households' utility and firms' profits are maximized. Thus, to find a system of equations that C_0 , N_0 , w_0 , and r_0 must solve in a balanced growth path, we must characterize and solve the household and firm problems. To start, the household problem is given by

$$\max_{\{C_t, K_{t+1}^s, N_t^s\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta_t u(C_t, 1-N_t) \text{ s.t. } \sum_{t=0}^{\infty} p_t (C_t + K_{t+1}) \leq \sum_{t=0}^{\infty} p_t (r_t K_t + w_t A_t N_t) + \pi_0$$

And the firm's problem is:

$$\max_{\{K_t^d, N_t^d\}_{t=0}^{\infty}} \pi_0 = \sum_{t=0}^{\infty} p_t (Y_t - r_t K_t^d - w_t N_t^d) \text{ s.t. } Y_t \leq F(K_t^d, A_t N_t^d)$$

Where, recognizing that π_0 is monotone in Y_t , the firm's problem can be reduced to:

$$\max_{\{K_t^d, N_t^d\}_{t=0}^{\infty}} \pi_0 = \sum_{t=0}^{\infty} p_t (F(K_t^d, A_t N_t^d) - r_t K_t^d - w_t N_t^d)$$

Since the firm is a price-taker whose decision in each period has no bearing on its conditions in any other period, the firm's problem can be solved by solving a single arbitrary period, t , using first-order conditions. For all choice variables, X , let $\frac{X_t}{A_t} = x_t$:

$$\max_{\{k_t^d, N_t^d\}_{t=0}^{\infty}} \pi_0 = \sum_{t=0}^{\infty} A_t p_t \left(F(k_t^d, N_t^d) - r_t k_t^d - \frac{w_t}{A_t} N_t^d \right)$$

$$\begin{aligned}
K_t^d : \quad & A_t p_t F_K(k_t^d, N_t^d) - A_t p_t r_t = 0 \\
& F_K(k_t^d, N_t^d) = r_t \\
N_t^d : \quad & A_t p_t F_N(k_t^d, N_t^d) - p_t w_t = 0 \\
& F_N(k_t^d, N_t^d) = \frac{w_t}{A_t}
\end{aligned}$$

This solution ensures that that $\pi_0 = 0$. Assuming that the utility function is concave, strictly increasing, and differentiable, the constrating of the household problem holds with equality and an interior solution exists. Given the firm's solution, we can solve the constraint as:

$$\begin{aligned}
C_t &= r_t K_t^s + w_t A_t N_t^s - K_{t+1}^s \\
c_t &= r_t k_t^s + w_t N_t^s - k_{t+1}^s
\end{aligned}$$

Such that the household's problem becomes:

$$\max_{\{k_{t+1}^s, N_t^s\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta_t u(A_t(r_t k_t^s + w_t N_t^s - k_{t+1}^s), 1 - N_t)$$

With the Bellman equation:

$$V(k) = \max_{k', N} \{u(A(rk + wN - k'), N) + \beta V(k')\}$$

Which has the first-order conditions:

$$\begin{aligned}
k' : \quad & -u_c(Ac, N) + \beta V'(k') = 0 \\
\text{Envelope condition:} \quad & V'(k') = r' A' u'(A' c', N') \\
\Rightarrow \quad & u_c(Ac, N) = \beta r' A' u_c(A' c', N') \\
N : \quad & A w u_c(Ac, N) + u_N(Ac, N) = 0 \\
\Rightarrow \quad & -\frac{u_N(Ac, N)}{u_c(Ac, N)} = w A
\end{aligned}$$

Where the final equation determines the household's optimal level of consumption given wages and productivity. In equilibrium, all markets clear:

$$\begin{aligned}
K_t^s &= K_t^d & (\text{Capital}) \\
N_t^s &= N_t^d & (\text{Labor}) \\
C_t + K_{t+1} &= F(K_t, A_t N_t) & (\text{Goods})
\end{aligned}$$

And each initial choice variable, N_0 and C_0 , and price, w_0 and r_0 , satisfies the firm and household optimization conditions for a balanced growth path:

$$\begin{aligned}
F_K(k_0^d, N_0^d) &= r_0 \\
F_N(k_0^d, N_0^d) &= \frac{w_0}{A_0} \\
-\frac{u_N(A_0 c_0, N_0)}{u_c(A_0 c_0, N_0)} &= w_0 A_0
\end{aligned}$$

- (f)

Question 2

- (a) (I think this is what the state-contingent problem is)

$$\max_{\{c_t, s_t\}_{t=0}^{\infty}} \mathbb{E} \left[\sum_{t=0}^{\infty} \beta^t \frac{c_t^{1-\gamma}}{1-\gamma} \right] \text{ s.t. } x_{t+1} = A_t s_t, s_t \leq x_t - c_t$$

The expectations operator in this case averages utility in each period across states of the world, weighting by that state's probability. Specifically, for each t , letting $c_t = A_{t-1}s_{t-1} - s_t$:

$$\mathbb{E} \left[\beta^t \frac{(A_{t-1}s_{t-1} - s_t)^{1-\gamma}}{1-\gamma} \right] = \pi \left[\beta^t \frac{(A_h s_{t-1} - s_t)^{1-\gamma}}{1-\gamma} \right] + (1-\pi) \left[\beta^t \frac{(A_l s_{t-1} - s_t)^{1-\gamma}}{1-\gamma} \right]$$

- (b) In each period, the consumer's consumption-savings problem is constrained by her savings in the last period, multiplied by draw of A she received that period. Thus, her relevant state variable is $A_{t-1}s_{t-1}$. The Bellman for this problem, letting A^{-1} and s^{-1} be the values for A and s in the prior period, is:

$$V(A^{-1}s^{-1}) = \max_{s'} \left\{ \frac{(A^{-1}s^{-1} - s')^{1-\gamma}}{1-\gamma} + \beta [\pi V(A_h s') + (1-\pi)V(A_l s')] \right\}$$

Given that $\gamma \in (0, 1)$, $\frac{(A^{-1}s^{-1} - s')^{1-\gamma}}{1-\gamma}$ is clearly concave, increasing, and continuous in s^{-1} . [how do I prove this?]

- (c)
- (d)

Question 3

- (a)
- (b)
- (c)
